## Solution of a Problem in Concurrent Programming Control

E. W. Dijkstra
*Technological University, Eindhoven, The Netherlands*

A number of mainly independent sequential-cyclic processes with restricted means of communication with each other can be made in such a way that at any moment one and only one of them is engaged in the "critical section" of its cycle.

### Introduction

Given in this paper is a solution to a problem for which, to the knowledge of the author, has been an open question since at least 1962, irrespective of the solvability. The paper consists of three parts: the problem, the solution, and the proof. Although the setting of the problem might seem somewhat academic at first, the author trusts that anyone familiar with the logical problems that arise in computer coupling will appreciate the significance of the fact that this problem indeed can be solved.

### The Problem

To begin, consider $N$ computers, each engaged in a process which, for our aims, can be regarded as cyclic. In each of the cycles a so-called "critical section" occurs and the computers have to be programmed in such a way that at any moment only one of these $N$ cyclic processes is in its critical section. In order to effectuate this mutual exclusion of critical-section execution the computers can communicate with each other via a common store. Writing a word into or nondestructively reading a word from this store are undividable operations; i.e., when two or more computers try to communicate (either for reading or for writing) simultaneously with the same common location, these communications will take place one after the other, but in an unknown order.

The solution must satisfy the following requirements.

(a) The solution must be symmetrical between the $N$ computers; as a result we are not allowed to introduce a static priority.

(b) Nothing may be assumed about the relative speeds of the $N$ computers; we may not even assume their speeds to be constant in time.

(c) If any of the computers is stopped well outside its critical section, this is not allowed to lead to potential blocking of the others.

(d) If more than one computer is about to enter its critical section, it must be impossible to devise for them such finite speeds, that the decision to determine which one of them will enter its critical section first is postponed until eternity. In other words, constructions in which "After you"-"After you"-blocking is still possible, although improbable, are not to be regarded as valid solutions.

We beg the challenged reader to stop here for a while and have a try himself, for this seems the only way to get a feeling for the tricky consequences of the fact that each computer can only request one one-way message at a time. And only this will make the reader realize to what extent this problem is far from trivial.

### The Solution

The common store consists of:

"**Boolean array** $b, c[1{:}N]$; **integer** $k$"

The integer $k$ will satisfy $1 \leq k \leq N$, $b[i]$ and $c[i]$ will only be set by the $i$th computer; they will be inspected by the others. It is assumed that all computers are started well outside their critical sections with all Boolean arrays mentioned set to **true**; the starting value of $k$ is immaterial.

The program for the $i$th computer $(1 \leq i \leq N)$ is:

```
"integer j;
Li0:  b[i] := false;
Li1:  if k ≠ i then
Li2:  begin c[i] := true;
Li3:  if b[k] then k := i;
      go to Li1
      end
        else
Li4:  begin c[i] := false;
        for j := 1 step 1 until N do
          if j ≠ i and not c[j] then go to Li1
      end;
      critical section;
      c[i] := true;  b[i] := true;
      remainder of the cycle in which stopping is allowed;
      go to Li0"
```

### The Proof

We start by observing that the solution is safe in the sense that no two computers can be in their critical section simultaneously. For the only way to enter its critical section is the performance of the compound statement $Li4$ without jumping back to $Li1$, i.e., finding all other $c$'s **true** after having set its own $c$ to **false**.

The second part of the proof must show that no infinite "After you"-"After you"-blocking can occur; i.e., when none of the computers is in its critical section, of the computers looping (i.e., jumping back to $Li1$) at least one—and therefore exactly one—will be allowed to enter its critical section in due time.

If the $k$th computer is not among the looping ones, $b[k]$ will be **true** and the looping ones will all find $k \neq i$. As a result one or more of them will find in $Li3$ the Boolean $b[k]$ **true** and therefore one or more will decide to assign "$k := i$". After the first assignment "$k := i$", $b[k]$ becomes **false** and no new computers can decide again to assign a new value to $k$. When all decided assignments to $k$ have been performed, $k$ will point to one of the looping computers and will not change its value for the time being, i.e., until $b[k]$ becomes **true**, viz., until the $k$th computer has completed its critical section. As soon as the value of $k$ does not change any more, the $k$th computer will wait (via the compound statement $Li4$) until all other $c$'s are **true**, but this situation will certainly arise, if not already present, because all other looping ones are forced to set their $c$ **true**, as they will find $k \neq i$. And this, the author believes, completes the proof.

is the problem **solved**?
